Summary

- [Here](#) is a course website.
- [Here](#) is a course program.
- We expect some theoretical knowledge
  - read 2. chapter from [Gussenhoven, Jacobs 2011]
  - be able to use IPA symbols
- We expect some basic R skills:
  - import .csv files to R
  - dplyr, ggplot2

# Phonetics?...

Phonetics

Phonology

from <http://specgram.com/CLIII.1/09.parenchyma.cartoon.e.html>

Phonetics is generally assumed to be a subfield that deals with **articulatory, acoustic and perceptual** aspects of phonological units. Phonology and phonetics together are supposed to describe organization of sounds in languages.

This course is about **acoustic phonetics**.

# Simple Harmonic Motion

**Periodic Motion** is any type of motion that repeats itself after successive equal time intervals.

**Simple Harmonic Motion** is specific type of periodic motion that arises from

- existence of some **equilibrium position** for a described object;
- **linear restoring force** that tending to pull the described object back to its equilibrium position.

Graph of Simple Harmonic Motion

# Simple Harmonic Motion

**Amplitude** is the maximum displacement of the equilibrium position.

**Period (T)** is the duration of time of one cycle in a repeating event. (s)

**Frequency (f)** is the number of period (cycles) per second. (Hz)

$$f = \frac{1}{T}$$

$$T = \frac{1}{f}$$

Graph of Simple Harmonic Motion

# Sound as SHM

We can correlate the physical properties of sound waves with our perception:

- We perceive changes in frequency as **pitch**
- We perceive changes in amplitude as **loudness**

Model

Summary

# Phase of SHM

One period of SHM can be divided into  $360^\circ$  of **phase  $\phi$** .

# SHMs comparison

These SHM curves are out of phase

Solid SHM curve is in  $90^\circ$  phase ahead

# Wave representation

Waves can be represented by formula:

$$s(t) = A \times \cos(2\pi ft + \phi)$$

- $A$  — amplitude
- $f$  — is the fundamental frequency
- $\phi$  — phase
- $t$  — time

# Harmonic motion

Model

Summary

## Damped harmonic motion

## Forced harmonic motion

# Harmonic motion

Harmonic motions are closely related with the phenomena of **resonance** and **antiresonance**.

**Resonance** is a phenomenon in which a vibrating system or external force drives another system to oscillate with greater amplitude at specific frequencies.

**Antiresonance** is a phenomenon in which a vibrating system or external force drives another system to oscillate with smaller amplitude at specific frequencies.

# Addition of waves

# Addition of waves

# Addition of waves

# Addition of waves

# Beats

**Beats** is a phenomenon of the change in amplitude of the sum of two waves with slightly different frequencies.

**Fourier Transform** allows to extract components of the complex wave.

**Fourier Transform** allows to extract components of the complex wave.

Summary

# Spectral slices

Spectrograms are differ in window length

# Spectrograms

## Syllable [ka]

# Not by Fourier alone

Conventional spectrogram and Zhao-Atlas-Marks distribution of the English word *had*, computed using a Kaiser tapering function.

from [Fulop 2011: 119]

# Not by Fourier alone

Conventional and reassigned spectrograms of the English word *right*

from [Fulop 2011: 142]

# Source-Filter Model of Speech Production

The output energy (at the mouth) for a given frequency is equal to the amplitude the source harmonic, multiplied by the magnitude of the filter function for that the frequency.

# Summary

- sounds are waves (with amplitude, frequency and phase)
- simple waves can be combined to the complex one
- Fourier transform allows to extract components of the complex wave
- It is not only Fourier transform that allows to extract components of the complex wave
- Source-Filter Model: vocal tract is a resonator that filters some frequencies of the wave produced by vocal folds vibration.
